

# The *n*-Point Condition and Rough CAT(0)

#### **Abstract**

We show that for  $n \geq 5$ , a length space  $(X, d)$  satisfies a rough *n*-point condition if and only if it is rough CAT(0). As a consequence, we show that the class of rough CAT(0) spaces is closed under reasonably general limit processes such as pointed and unpointed Gromov-Hausdorff limits and ultralimits.

#### **Keywords**

CAT(0) space, rough CAT(0) space, Gromov hyperbolic space, Gromov-Hausdorff limit, ultralimit

# 1. Introduction

Gromov hyperbolic spaces and CAT(0) spaces have been intensively studied; see [\[4\]](#page-9-0), [\[6\]](#page-9-1), [\[10\]](#page-10-0), [\[3\]](#page-9-2) and the references<br>therein. Their respective theories display some common features, notably the canonical boundary topologi  $CAT(0)$  spaces, a class of length spaces that properly contains both  $CAT(0)$  spaces and those Gromov hyperbolic spaces that are length spaces, were introduced by the first author and Kurt Falk in a pair of papers to unify as much as possible of the theories of  $CAT(0)$  and Gromov hyperbolic spaces: the basic "finite distance" theory of rough  $CAT(0)$  spaces was developed in  $[1]$ , and the boundary theory was developed in  $[2]$ . As in the earlier papers, we usually write rCAT(0) in place of rough CAT(0) below. Rough CAT(0) is closely related to the class of bolic spaces of Kasparov and Skandalis [8], [9] that was introduced in the context of their work on the Baum-Connes and Novikov Conjectures, and is also related [9] that was interacted in the context [of](#page-9-5) t[he](#page-9-6) context of the context of the context of the context of the context<br>to Gromov's class of CAT(-1,*ε*) spaces [7], [5].<br>One see is the theory dyvelenced so far is the change of

One gap in the theory developed so far is the absence of results indicating that the class of rCAT(0) spaces is closed<br>under reasonably general limit processes such as pointed and unpointed Gromov-Hausdorff limits and ultr purpose of this paper is to fill that gap.

purpose of this paper is to fill that gap. T[he](#page-9-2) fact that the CAT(0) class is closed under such limit processes is a consequence of the following well-known result (for which, see  $[3, 11.1.11]$ ):

### <span id="page-0-0"></span>*Theorem A.*

*A complete geodesic metric space <sup>X</sup> is CAT(0) if and only if it satisfies the* <sup>4</sup>*-point condition.*

In  $[1,$  Theorem 3.18], it was shown that a rough variant of the 4-point condition is quantitatively equivalent to a weak version of rCAT(0), and it follows that the class of weak rCAT(0) spaces is closed under reasonably However it seems difficult to decide whether or not all weak rCAT(0) spaces are necessarily rCAT(0). To establish similar  $\frac{1}{2}$  and  $\frac{1}{2}$  are prope[rti](#page-1-0)es for rCAT(0), we prove the following rough analogue to Theorem A; rough *n*-point conditions are defined in Section 2.

theorem and discuss its limit slocuse consequences in Section  $\Lambda$ . theorem and discuss its limit closure consequences in Section 4.

# <span id="page-1-0"></span>2. Preliminaries

Whenever we write  $\mathbb{R}^2$ section, *X* is a metric space with metric *d* attached; any extra assumptions on *d* will be explicitly stated.<br>A h chart essement  $h > 0$  in *X* is a nath  $w([0, l] \times Y, l > 0$  setisfying. A *h*-short segment,  $h \geq 0$ , in X is a path  $\gamma : [0, L] \rightarrow X$ ,  $L \geq 0$ , satisfying

len(*γ*) *<sup>≥</sup> <sup>d</sup>*(*γ*(0)*, γ*(*L*)) *<sup>≥</sup>* len(*γ*) *<sup>−</sup> h.*

We denote *h*-short segments connecting points *x*,  $y \in X$  by  $[x, y]_h$ . It is convenient to use  $[x, y]_h$  also for the image of this path, so instead of writing  $z = γ(t)$  for some  $0 \le t \le L$ , we often write  $z ∈ [x, y]_h$ . Given such a path  $γ$  and point  $z = \gamma(t)$ , we denote by  $[x, z]_h$  and  $[z, y]_h$  respectively the subpaths  $\gamma|_{[0,t]}$  and  $\gamma|_{[t,L]}$ , respectively; note that both of these are *h*-short segments. A 0-short segment is called a *geodesic segment*, and we write  $[x, y]$  in place of  $[x, y]$ <sup>0.</sup><br>A metric space  $(Y, d)$  is a spectatio space if for we write  $(Y, d)$  there exists the spectation segment  $[y$ 

A metric space (*X, d*) is a *geodesic space* if for every *x, y <sup>∈</sup> <sup>X</sup>*, there exists at least one geodesic segment [*x, y*]. More generally,  $(X, d)$  is a *length space* if for every  $x, y \in X$  and every  $h > 0$ , there exists a *h*-short path  $[x, y]_h$ .

A h-short triangle  $T := T_h(x_1, x_2, x_3)$  with vertices  $x_1, x_2, x_3 \in X$  is a collection of h-short segments  $[x_1, x_2]_h$ ,  $[x_2, x_3]_h$ , and [*x*3*, x*1]*<sup>h</sup>* (the *sides* of *<sup>T</sup>* ). Given such a *<sup>h</sup>*-short triangle *<sup>T</sup>* , a *comparison triangle* will mean a Euclidean triangle  $\overline{T} := T(\overline{x}_1, \overline{x}_2, \overline{x}_3)$  in  $\mathbb{R}^2$ , such that  $|\overline{x}_i - \overline{x}_j| = d(x_i, x_j)$ ,  $i, j \in \{1, 2, 3\}$ . Furthermore, we say that  $\overline{u} \in [\overline{x}_i, \overline{x}_j]$  is a comparison point for  $u \subset [u, u]$ , if *comparison point* for  $u \in [x_i, x_j]_h$ , if

$$
|\bar{x}_i - \bar{u}| \leq \text{len}([x_i, u]_h) \quad \text{and} \quad |\bar{u} - \bar{x}_j| \leq \text{len}([u, x_j]_h).
$$

A *geodesic triangle*  $T = T(x, y, z)$  is just a 0-short triangle. Note that in this case if  $\overline{T} := T(\overline{x}_1, \overline{x}_2, \overline{x}_3)$  in  $\mathbb{R}^2$ <br>composison triangle and  $\overline{x} \in [\overline{x}, \overline{x}_1]$  is a composison point for  $y \in [x, y]$  than comparison triangle, and  $\bar{u} \in [\bar{x}_i, \bar{x}_j]$  is a *comparison point* for  $u \in [x_i, x_j]$ , then  $\bar{u} \in [\bar{x}_i, \bar{x}_j]$  is uniquely determined by the example and  $\bar{u} \in [\bar{x}_i, \bar{x}_j]$ . equation  $|\bar{x}_i - \bar{u}| = d(u, x_i)$ .

A geodesic space  $(X, d)$  is a *CAT(0) space* if given any geodesic triangle  $T = T(x, y, z)$  with comparison triangle  $\overline{I} = \overline{I}(\overline{x}, \overline{u}, \overline{z})$ , and any two points  $u \in [x, y]$  and  $v \in [x, z]$ , we have  $d(u, v) \leq |\overline{u} - \overline{v}|$ , where  $\overline{u}$  and  $\overline{v}$  are comparison points for *<sup>u</sup>* and *<sup>v</sup>*.

## *Definition 2.1.*

Given  $C > 0$ , and a function  $H : X \times X \times X \to (0, \infty)$ , a length space  $(X, d)$  is said to be a  $C$ -rCAT(0; H) space if the following *C-rough CAT(0) condition* is satisfied:

$$
d(u,v)\leq |\bar{u}-\bar{v}|+C,
$$

*• x, y, z <sup>∈</sup> <sup>X</sup>*;

- $\overline{I} := T_h(x, y, z)$  is a *h*-short triangle, where  $h = H(x, y, z)$ ;
- $\bullet$   $\bar{T} := T(\bar{x}, \bar{y}, \bar{z})$  is a comparison triangle in  $\mathbb{R}^2$  associated with  $T$ ;
- *• u, v* lie on different sides of *<sup>T</sup>* ;
- $\bar{u}, \bar{v} \in \bar{T}$  are comparison points for *u*, *v*, respectively;

*.*

We call  $(T_h(x, y, z), u, v)$  the *metric space data* and  $(T(\bar{x}, \bar{y}, \bar{z}), \bar{u}, \bar{v})$  the *comparison data*.

#### *Definition 2.2.*

Given  $C > 0$ , a length space *X* is  $C$ -rCAT(0; \*) if there exists  $H : X \times X \times X \to (0, \infty)$  such that *X* is  $C$ -rCAT(0; *H*). (*X, d*) is *C-rCAT*(0) if it is *<sup>C</sup>*-rCAT(0; *<sup>H</sup>*) with

$$
H(x, y, z) = \frac{1}{1 \vee d(x, y) \vee d(x, z) \vee d(y, z)}
$$

Let us make some remarks about the above definitions. First, every CAT(0) space is *<sup>C</sup>*-[rCA](#page-9-3)T(0) and *<sup>C</sup> 0* -rCAT(0; *<sup>∗</sup>*), with *C* = 2 +  $\sqrt{3}$  and *C*' > 0 arbitrary; this follows from Theorem 4.5 and Corollary 4.6 of [\[1\]](#page-9-3). Trivially *C*-rCAT(0) implies  $C \times CAT(0, 1)$  conversely  $C \times CAT(0, 1)$  implies  $C \times CAT(0)$  for  $C \times CAT(0)$  for  $C \times CAT(0)$  and  $C = 2 + \sqrt{3}$  and  $C \ge 0$  and and  $\sqrt{9}$ , this follows from Theorem 1.5 and ecolodary<br>  $C$ -rCAT(0; *\**). Conversely,  $C$ -rCAT(0; *\**) implies  $C'$ -rCAT(0) for  $C' := 3C + 2 + \sqrt{2}$ <br>
The symbiotic *U* in the rCAT(0) condition

 $\overline{\text{The explicit H in the rAT(0) condition has proved to be useful, but one situation where rCAT(0; *) is needed is when the explicit H in the rAT(0) condition where  $\overline{\text{CAT(0)}} = \frac{1}{2}$$  $\overline{\text{The explicit H in the rAT(0) condition has proved to be useful, but one situation where rCAT(0; *) is needed is when the explicit H in the rAT(0) condition where  $\overline{\text{CAT(0)}} = \frac{1}{2}$$  $\overline{\text{The explicit H in the rAT(0) condition has proved to be useful, but one situation where rCAT(0; *) is needed is when the explicit H in the rAT(0) condition where  $\overline{\text{CAT(0)}} = \frac{1}{2}$$ the parameter *<sup>C</sup>* is close to 0. In particular, we show in Theorem 4.16 that if (*X<sup>n</sup>*) is a sequence of *<sup>C</sup><sup>n</sup>*-rCAT(0; *<sup>∗</sup>*) spaces with  $C_n \to 0$ , then under rather general conditions the resulting limit space is necessarily CAT(0). *A fortiori*, we could change the *<sup>C</sup><sup>n</sup>*-rCAT(0; *<sup>∗</sup>*) hypothesis in this result to *<sup>C</sup><sup>n</sup>*-rCAT(0), but such a variant is of no real interest since a length space satisfying a *<sup>C</sup>*-rCAT(0) condition for *C <* <sup>1</sup>*/*<sup>2</sup> has diameter at most *<sup>C</sup>* (as a hint, in a space of diameter larger than this, consider a triangle  $T(x, x, x)$  containing a side  $[x, x]$  that moves away from x and back again). In particular, only a one-point space can be  $C$ -rCAT(0) for all  $C > 0$ . By contrast, the class of spaces that are  $C$ -rCAT(0;  $*$ ) for all *C >* <sup>0</sup> is quite large: it includes, for instance, all CAT(0) spaces (as mentioned above), as well as examples such as the *deleted Euclidean plane*  $D := \mathbb{R}^2 \setminus \{0\}$ . That  $D$  is an example follows from a more general principle: if  $(X, d)$  is<br>C  $\pi CAT(0, t)$  for all  $C > 0$  and a subpapea  $(S, d)$  of  $Y$  is also a langth appea than  $\pi$  fac  $C$ -rCAT(0;  $*$ ) for all  $C > 0$ , and a subspace  $(S, d)$  of X is also a length space then, *a fortiori*, S is  $C$ -rCAT(0;  $*$ ) for all *C >* <sup>0</sup> because the set of *<sup>h</sup>*-short paths between *x, y <sup>∈</sup> <sup>S</sup>* is a subset of the set of *<sup>h</sup>*-short paths between *<sup>x</sup>* and *<sup>y</sup>* in *<sup>X</sup>*. We now introduce the concept of  $C$ -rough subembeddings (into  $\mathbb{R}^2$ ), which we use to define rough *n*-point conditions.

#### *Definition 2.3.*

Let  $(X, d)$  be a metric space,  $C \ge 0$  and  $n \ge 3$  be an integer. Suppose  $x_i \in X$  and  $\overline{x}_i \in \mathbb{R}^2$  for  $0 \le i \le n$ , with  $x_0 = x_n$ and  $\overline{x}_0 = \overline{x}_n$ . We say that  $(\overline{x}_1, \overline{x}_2, ..., \overline{x}_n)$  is a *C-rough subembedding* of  $(x_1, x_2, ..., x_n)$  into  $\mathbb{R}^2$  if

### *Definition 2.4.*

Let  $n \geq 3$  be an integer. A metric space  $(X, d)$  satisfies the *C-rough n-point condition*, where  $C \geq 0$ , if every *n*-tuple in *X* has a *C*-rough subembedding into  $\mathbb{R}^2$ . We say that *X* satisfies a rough *n*-point condition if it satisfies a *C*-rough *<sup>n</sup>*-point condition for some *<sup>C</sup>*. The *n-point condition* is the 0-rough *<sup>n</sup>*-point condition.

We note that our not[ion](#page-9-6) of a rough 5-point condition is somewhat analogous to the *mesoscopic curvature* notion of Delzant and Gromov [5] which they call CAT*<sup>ε</sup>*(*κ*), although that paper is concerned with *κ <* 0, whereas our notion corresponds to  $\kappa = 0$ .

Before proceeding further, let us discuss these conditions. If we vary just one of the parameters *<sup>C</sup>* and *<sup>n</sup>* in the *<sup>C</sup>*-rough *<sup>n</sup>*-point condition, it is easy to see that decreasing *<sup>C</sup>* or increasing *<sup>n</sup>* gives a stronger condition; note that to deduce the *<sup>C</sup>*-rough (*<sup>n</sup> <sup>−</sup>* 1)-point condition from the *<sup>C</sup>*-rough *<sup>n</sup>*-point condition, we simply take *<sup>x</sup><sup>n</sup>* <sup>=</sup> *<sup>x</sup>n−*1. The 3-point condition

is satisfied by all metric spaces. For geodesic spaces, the 4-point condition is equivalent to CAT(0); see [\[3,](#page-9-2) II.1.11]. For length spaces, a *<sup>C</sup>*-rough 4-point condition is quantitatively equivalent to a weaker version of rCAT(0) in which the *<sup>C</sup>*-rCAT(0) condition is assumed for metric space data  $(T_h(x, y, z), u, v)$  only when *v* is one of the vertices *x*, *y*, *z*; see [\[1,](#page-9-3) Theorem 3.18]. However it seems difficult to decide whether or not weak rCAT(0) spaces are necessarily rCAT(0). We do not addres paper, but we will show that, among length spaces, rCAT(0) is quantitatively equivalent to a rough *n*-point condition

for  $n > 4$ . Thus the class of weak rCAT(0) spaces coincides with the class of length spaces satisfying a rough 4-point condition, and the class of rCAT(0) spaces coincides with the class of length spaces satisfying an *<sup>n</sup>*-point condition for any value (or all values) of *n >* 4, but we cannot say whether or not a rough 4-point condition implies a rough *<sup>n</sup>*-point condition for  $n > 4$ .<br>The proof of Theorem 4.2 will require the following simple results.

The proof of Theorem 4.2 will require the following simple results.

## <span id="page-3-1"></span>*Lemma 2.5.*

Suppose  $A, B, B', C \in \mathbb{R}^2$  such that B and B' lie on opposite sides of the line through A and C. Suppose that the sum *of the angles at <sup>C</sup> of the triangles <sup>T</sup>* (*A, B, C*) *and <sup>T</sup>* (*A, B<sup>0</sup> , C*) *is at least π. Then*

$$
|B - C| + |C - B'| \le |B - A| + |A - B'|.
$$

In fact, we need only the following immediate corollary; below, a *filled polygon* in the Euclidean plane means a polygon plus its bounded complementary component.

#### <span id="page-3-4"></span>*Corollary 2.6.*

Suppose  $P$ ,  $P'$  are filled polygons in  $\mathbb{R}^2$  such that:

- (a)  $P$  and  $P'$  share a side  $[A, C]$ , and lie on opposite sides of  $[A, C]$ ;
- *(b)* the sum of the interior angles at C in P and P' is at least  $\pi$ .

Let Q be the filled polygon P  $\cup$  P', and let B, B' be the vertices other than A that are adjacent as vertices to C in P *and P 0 , respectively. Then the geodesic path from B to B 0 in <sup>Q</sup> consists of the union of the line segments* [*B, C*] *and*  $[C, B']$ .

## <span id="page-3-0"></span>3. Two lemmas

The proof of Theorem [1.1](#page-1-1) requires the following two lemmas. The first is a restatement of [\[1,](#page-9-3) Lemma 3.12].

## <span id="page-3-2"></span>*Lemma 3.1.*

Let x, y be a pair of points in the Euclidean plane  $\mathbb{R}^2$ , with  $l := |x - y| > 0$ . Fixing  $h > 0$ , and writing  $L := l + h$ , let *<sup>γ</sup>* : [0*, L*] *<sup>→</sup>* <sup>R</sup> <sup>2</sup> *be a h-short segment from <sup>x</sup> to y, parameterized by arclength. Then there exists a map <sup>λ</sup>* : [0*, L*] *<sup>→</sup>* [*x, y*] *such that*  $\lambda(0) = x$ ,  $\lambda(L) = y$ , and

$$
|\lambda(t) - x| \leq |\gamma(t) - x|, \qquad 0 \leq t \leq L,
$$
  

$$
|\lambda(t) - y| \leq |\gamma(t) - y|, \qquad 0 \leq t \leq L,
$$
  

$$
\delta(t) := \text{dist}(\gamma(t), \lambda(t)) \leq M := \frac{1}{2}\sqrt{2lh + h^2}, \qquad 0 \leq t \leq L.
$$

*In particular if h* =  $\varepsilon$ /(1  $\vee$  *l*) *for some*  $0 < \varepsilon \le 1$ , *then*  $\delta(t) \le \sqrt{3\varepsilon}/2$  *for all*  $0 \le t \le L$ .

## <span id="page-3-3"></span>*Lemma 3.2.*

Assume  $x_i$ ,  $x'_i \in \mathbb{R}^2$  for  $i = 0, 1, 2$ , with  $u_i \in [x_0, x_i]$  and  $u'_i \in [x'_0, x'_i]$  for  $i = 1, 2$  and let

$$
h = \frac{\varepsilon}{1 \vee |x'_0 - x'_1| \vee |x'_0 - x'_2|} \,,
$$

*for some*  $0 < \varepsilon \leq 1$ *. Suppose further that* 

$$
\begin{aligned} |x_1 - x_2| &= |x_1' - x_2'| \,, \\ |x_0' - x_i'| &\le |x_0 - x_i| \le |x_0' - x_i'| + h, \qquad i = 1, 2 \,. \end{aligned}
$$

**VERSITA** 

Stephen M. Buckley, Bruce Hanson

*and*

*|u<sup>i</sup> <sup>−</sup> <sup>x</sup>*0*<sup>|</sup>*  $|x_0 - x_i|$  $|u'_i - x'_0|$  $\frac{1}{2}$  $\frac{|x_i - x_{i+1}|}{|x'_0 - x'_i|}$ ,  $i = 1, 2$ .

*Then*  $|u_1 - u_2| \le |u'_1 - u'_2| + \sqrt{3\varepsilon}$ .

*Proof.* Set

$$
s = \frac{|u_1 - x_0|}{|x_1 - x_0|} = \frac{|u'_1 - x'_1|}{|x'_1 - x'_0|}
$$

$$
t = \frac{|u_2 - x_0|}{|x_2 - x_0|} = \frac{|u'_2 - x'_0|}{|x'_2 - x'_0|}
$$

We assume without loss of generality that *<sup>s</sup> <sup>≤</sup> <sup>t</sup>*. An elementary calculation using the parallelogram law shows that given *x*, *y*, *z* in the Euclidean plane with  $w \in [y, z]$  and  $|w - y| = r|z - y|$  we have

<span id="page-4-1"></span>
$$
|x - w|^2 = (1 - r)|x - y|^2 + r|x - z|^2 - r(1 - r)|y - z|^2.
$$
\n(3.3)

*.*

Using  $(3.3)$  twice, we get

<span id="page-4-3"></span>
$$
|u_1 - u_2|^2 = st|x_1 - x_2|^2 + t^2 \left(1 - \frac{s}{t}\right)|x_0 - x_2|^2 - st\left(1 - \frac{s}{t}\right)|x_0 - x_1|^2 \tag{3.4}
$$

and similarly

<span id="page-4-2"></span>
$$
|u'_1 - u'_2|^2 = st|x'_1 - x'_2|^2 + t^2 \left(1 - \frac{s}{t}\right)|x'_0 - x'_2|^2 - st\left(1 - \frac{s}{t}\right)|x'_0 - x'_1|^2. \tag{3.5}
$$

 $\Box$ 

 $\int u_1 - u_2 = |u'_1 - u'_2|$  $\left( \frac{2}{2} \right] + d$  and subtracting [\(3.5\)](#page-4-2) from [\(3.4\)](#page-4-3), we get

$$
2d|u'_1 - u'_2| + d^2 = t^2 \left(1 - \frac{s}{t}\right) \left(|x_0 - x_2|^2 - |x'_0 - x'_2|^2\right) -
$$
  

$$
- st \left(1 - \frac{s}{t}\right) \left(|x_0 - x_1|^2 - |x'_0 - x'_1|^2\right)
$$
  

$$
\leq t^2 \left(1 - \frac{s}{t}\right) \left(|x_0 - x_2|^2 - |x'_0 - x'_2|^2\right)
$$
  

$$
\leq t^2 \left(1 - \frac{s}{t}\right) \left(2h|x'_0 - x'_2| + h^2\right) \leq 3\varepsilon.
$$

In particular *<sup>d</sup> <sup>≤</sup> √* <sup>3</sup>*ε*, as required.

# <span id="page-4-0"></span>4. Proof and consequences

Here we prove Theorem [1.1](#page-1-1) and discuss some consequences. First we need a definition.

## *Definition 4.1.*

Suppose  $(S, d_S)$  is a metric space, and that for  $i = 1, 2$ , we have a metric space  $(X_i, d_i)$ , a closed subspace  $S_i \subset X_i$ <br>conversive increasing  $f \in S_i$ ,  $S_i$ ,  $M_i$ , then define the slying of  $Y_i$ , and  $Y_i$ , then  $S_i$ ,  $S_i$ ,  $\sum_{i=1}^{\infty}$  or a metric operation of  $X_i$  and the difference of  $X_i$  and  $X_2$  along  $S_1$ ,  $S_2$  (denoted by  $X = X_1 \cup S_2$ ) as  $X_2 \cup X_3$  and  $X_2 \cup X_4$ . the quotient of the disjoint union of  $X_1$  and  $X_2$  under the identification of  $f_1(s)$  with  $f_2(s)$  for each  $s \in S$ . The glued metric *d* on *X* is defined by the equations  $d|_{X_i \times X_i} = d_i$ ,  $i = 1, 2$  and

$$
d(x_1, x_2) = \inf_{s \in S} (d_1(x_1, f_1(s)) + d_2(f_2(s), x_2)), \qquad x_1 \in X_1, x_2 \in X_2.
$$

62

We note the following easily verified facts about  $(X, d) := X_1 \sqcup_S X_2$  defined by gluing as above:

- *d* restricted to  $X_i$ ,  $i = 1, 2$ , coincides with  $d_i$ ;
- $\bullet$  every geodesic segment in  $X_i$ ,  $i = 1, 2$ , is also a geodesic segment in  $X$ .

We now prove the following slight improvement of Theorem [1.1.](#page-1-1)

#### <span id="page-5-4"></span>*Theorem 4.2.*

*Let*  $(X, d)$  *be a length space. If*  $n \geq 5$  *and*  $(X, d)$  *satisfies a C-rough n-point condition for some*  $C \geq 0$ *, then*  $(X, d)$  *is*  $C$ -rCAT(0) and C''-rCAT(0; \*), where  $C' = C + 2\sqrt{3}$  and  $C'' > C$  is arbitrary. Conversely, if  $(X, d)$  is  $C_0$ -rCAT(0; \*) for *some*  $C_0$  *>* 0*,* then for all  $n \geq 3$ ,  $(X, d)$  satisfies a *C*-rough *n*-point condition, where  $C = (n - 2)C_0$ .

*Proof.* Assume that (*X, d*) is a length space. We first prove the forward implication, so we assume that *n* ≥ 5 and that  $(X, d)$  satisfies a *C*-rough *n*-point condition for some  $C \ge 0$ . It follows trivially that  $(X, d)$  satisfies a *C*-rough 5-point condition. Let  $T := T_h(x, y, z)$  be a *h*-short geodesic triangle in *X*, where

$$
h = H(x, y, z) := \frac{\varepsilon}{1 \vee d(x, y) \vee d(x, z) \vee d(y, z)}\tag{4.3}
$$

and  $0 < \varepsilon \le 1$  is fixed but arbitrary. Assume also that  $u \in [x, y]_h$  and  $v \in [x, z]_h$ . Let  $(x', u', y', z', v')$  be a C-rough<br>subambadding of  $(x, y, y, y, x') = (x, u, u, z, u)$  into  $\mathbb{R}^2$  so in particular we have subembedding of  $(x_1, x_2, x_3, x_4, x_5) = (x, u, y, z, v)$  into  $\mathbb{R}^2$ , so in particular we have

$$
d(x, y) \le |x'-y'|
$$
,  $d(x, z) \le |x'-z'|$ ,  $d(y, z) = |y'-z'|$ ,

and

<span id="page-5-2"></span>
$$
d(u, v) \le |u' - v'| + C. \tag{4.4}
$$

**VERSITA** 

From the definition of a *<sup>C</sup>*-rough subembedding and the fact that *<sup>T</sup>* is *<sup>h</sup>*-short, it fo[llow](#page-3-2)s that the piecewise linear paths  $\gamma_1 = [x', u'] \cup [u', y']$  and  $\gamma_2 = [x', v'] \cup [v', z']$  are both *h*-short. Thus, by Lemma 3.1 we can choose  $u'' \in [x', y']$  and  $u'' \in [x', z']$  such that  $v'' \in [x', z']$  such that

<span id="page-5-3"></span>
$$
|u'-u''| \le \frac{\sqrt{3\varepsilon}}{2} \quad \text{and} \quad |v'-v''| \le \frac{\sqrt{3\varepsilon}}{2} \tag{4.5}
$$

and such that

<span id="page-5-0"></span>
$$
|u'' - x'| \le |u' - x'| \quad \text{and} \quad |u'' - y'| \le |u' - y'| \tag{4.6}
$$

and

$$
|v'' - x'| \le |v' - x'| \quad \text{and} \quad |v'' - z'| \le |v' - z'|. \tag{4.7}
$$

between points not connected by paths are indicated by dashed lines. Note that  $\{x', u', y'\}$  and  $\{x', v', z'\}$  might not be<br>settlinear points not connected by gaths are indicated by dashed lines. Note that  $\{x', u', y'\}$  and  $\{$ collinear sets even though  $u \in [x, y]_h$  and  $v \in [x, z]_h$ .

Now let  $\bar{T} = T(\bar{x}, \bar{y}, \bar{z})$  be a comparison triangle for  $T$  and choose  $\bar{u} \in [\bar{x}, \bar{y}]$ ,  $\bar{v} \in [\bar{x}, \bar{z}]$  satisfying:

<span id="page-5-1"></span>
$$
\frac{|\bar{u} - \bar{x}|}{|\bar{x} - \bar{y}|} = \frac{|u'' - x'|}{|x' - y'|} \quad \text{and} \quad \frac{|\bar{v} - \bar{x}|}{|\bar{x} - \bar{z}|} = \frac{|v'' - x'|}{|x' - z'|}. \tag{4.8}
$$

Since  $|\bar{x} - \bar{y}| = d(x, y) \le |x' - y'|$ , it follows from [\(4.6\)](#page-5-0) and [\(4.8\)](#page-5-1) that

*|u*

 $| \bar{u} - \bar{x} | \leq | u'' - x' | \leq | u' - x' |$ 

$$
|\bar{u} - \bar{y}| \le |u'' - y'| \le |u' - y'|,
$$

Stephen M. Buckley, Bruce Hanson

<span id="page-6-0"></span>*Fig 1.* Rough subembedding.

**VERSITA** 

so  $\bar{u}$  is a comparison point for  $u$ . Similarly  $\bar{v}$  is a comparison point for  $v$ . Finally, using [\(4.4\)](#page-5-2) and [\(4.5\)](#page-5-3), we see that

$$
d(u,v) \le |u'-v'| + C \le |u''-v''| + C + \sqrt{3\varepsilon}
$$

and so by Lemma [3.2,](#page-3-3) we get

$$
d(u,v) \leq |\bar{u} - \bar{v}| + C + 2\sqrt{3\varepsilon}.
$$

Thus  $(X, d)$  is C'-rCAT(0; \*), with  $C' = C + 2\sqrt{3\varepsilon}$ . Taking  $\varepsilon = 1$ , we see that X is C'-rCAT(0), where  $C' = C + 2\sqrt{3}$ . Letting  $\varepsilon > 0$  be sufficiently small, we see that *X* is *C*"-rCAT(0; \*).<br>We next preceed with the reverse impliestion as let us assume the

We next proceed with the reverse implication, so let us assume that  $(X, d)$  is *C'*-rCAT(0; \*). We will prove that  $(X, d)$ <br>catiofice the *C*, reveals a point condition where  $C_1$ ,  $(n-2)C_1$  and  $n \ge 2$ . satisfies the *C<sub>n</sub>*-rough *n*-point condition, where  $C_n := (n-2)C'$  and  $n \geq 3$ .<br>The areaf will involve induction, but vaing a stranger inductive hypothesis

The proof will involve induction, but using a stronger inductive hypothesis which involves not just a set of *<sup>n</sup>* points, but an *n*-gon with these points as vertices. Additionally, the inductive process requires us to establish simultaneously<br>a CAT(0) version of the result. Note that it suffices to prove the result for sets of distinct point  $\overline{C}$  and  $\overline{C}$  are  $\overline{C}$  and  $\overline{C}$  and  $\overline{C}$  are  $\overline{C}$  and  $\overline{C}$  are  $\overline{C}$  and  $\overline{C}$  are

Given  $u_1, u_2, \ldots, u_n \in X$ ,  $n \geq 3$ , we say that P is a h-short n-gon (with vertices  $u_1, u_2, \ldots, u_n = u_0$ ) if P is the union of *<sup>h</sup>*-short paths [*ui−*1*, u<sup>i</sup>* ]*<sup>h</sup>* for *<sup>i</sup>* = 1*,* <sup>2</sup>*, . . . , n*. An *<sup>n</sup>*-gon is *geodesic* if it is 0-short. We say that *<sup>h</sup>* is *suitably small* if  $h < H(u_i, u_j, u_k)$  for all  $1 \le i, j, k \le n$ .<br>Suppose

Suppose

- $Q$  is a geodesic *n*-gon with distinct vertices  $(v_i)_{i=1}^n$  and associated metric *d'*;
- *P* a *h*-short *n*-gon with distinct vertices  $(u_i)_{i=1}^n$  and associated metric *d*;
- $F: Q \rightarrow P$  is a map with  $F(v_i) = u_i$ ,  $1 \le i \le n$ .

Since a geodesic segment is isometrically equivalent to a segment on  $\mathbb R$ , we can view the restriction of F to a single side of *<sup>Q</sup>* as being a path, and hence define the path length len(*F*; *x, y*) to be the length of the associated path segment from  $F(x)$  to  $F(y)$ . We call  $F: Q \to P$  a *constant speed n-gon map* if P, Q, F are as above, and if for each  $1 \le i \le n$ there is a constant  $K_i$  such that len(F; x, y) =  $K_i d'(x, y)$  whenever  $x, y \in [v_{i-1}, v_i]$ . It is easy to see that, given any P, Q as above, a constant speed *<sup>n</sup>*-gon map always exists.

Given the following data:

*•* <sup>a</sup> *<sup>h</sup>*-short *<sup>n</sup>*-gon *<sup>P</sup>* with distinct vertices *<sup>u</sup>*1*, u*2*, . . . , u<sup>n</sup> <sup>∈</sup> <sup>X</sup>*, where (*X, d*) is a metric space and *<sup>h</sup>* is suitably small;

• a constant speed *n*-gon map  $F: Q \to P$ , where Q is a geodesic *n*-gon with distinct vertices  $v_1, v_2, \ldots, v_n \in Y$ , and  $(Y, d')$  is a CAT $(0)$  space, ) is a CAT( $\overline{0}$ ) space,

we define a hypothesis  $A_n(P, h; F, Q, d', C_n)$ :

$$
u_{i} = F(v_{i}), \t 1 \leq i \leq n,
$$
  
\n
$$
d(u_{i-1}, u_{i}) = d'(v_{i-1}, v_{i}), \t 1 \leq i \leq n,
$$
  
\n
$$
d(u_{1}, u_{i}) \leq d'(v_{1}, v_{i}), \t 2 \leq i \leq n,
$$
  
\n
$$
len([F(x), u_{i}]_{h}) \geq d'(x, v_{i}), \t x \in Q, v_{i} \text{ a vertex adjacent to } x,
$$
  
\n
$$
d(F(x), F(y)) \leq d'(x, y) + C_{n}, x, y \in Q.
$$
\n(4.10)

*The inductive hypothesis for n* is that for all *P, h* as above, there exist data (*F, Q, d'*) such that *A<sub>n</sub>*(*P, h*; *F, Q, d'*, *C<sub>n</sub>*) had a notice that *(O, d')* is a sensure Evolidaer n sen in  $\mathbb{R}^2$  with *d* holds, and such that  $(Q, d')$  is a convex Euclidean *n*-gon in  $\mathbb{R}^2$  with *d'*<br>decired *C*, rough a point embedding: the vertices of *Q* give the rough besired  $C_n$ -rough *n*-point embedding: the vertices of *Q* give the rough subembedding of the vertices of *P*. We have<br>defined the bunothesis  $A(B, b, E, Q, d', C)$  in the mere general center of a CAT(0) cases. Y because we wil defined the hypothesis  $A_n(P, h; F, Q, d', C_n)$  in the more general context of a CAT(0) space *Y* because we will need this<br>along the way

The CAT(0) version of our inductive hypothesis for *n* is that for all geodesic *n*-gons *P* as above, there exist data (*F*, *Q*, *d'*<br>such that *A* (*P*, O, *C, Q, d'*, 0) halds, and such that (*Q, d'*) is a seque undiv such that  $A_n(P, 0; F, Q, d', 0)$  holds, and such that  $(Q, d')$  is a conv[ex E](#page-7-0)uclidean *n*-gon in  $\mathbb{R}^2$  with *d'* being the Euclidean *n*-gon black with *b* and such that  $\frac{1}{2}$  with *d*  $\frac{1}{2}$  being the Euclidean *n*metric. Note also that with  $h = 0$  and  $C_n = 0$  we get equality in (4.9), and [\(4.10\)](#page-7-1) simplifies to

$$
d(F(x), F(y)) \le |x - y| \,. \tag{4.11}
$$

<span id="page-7-1"></span><span id="page-7-0"></span>**VERSITA** 

It is a routine task to use the *C*'-rCAT(0) condition to verify the inductive hypothesis for  $n = 3$  (and CAT(0) to verify the<br>CAT(0) verient of the inductive hypothesis for  $n = 2$ ) as assume that it halds for  $n = k \ge 3$ . CAT(0) variant of the inductive hypothesis for  $n = 3$ ), so assume that it holds for  $n = k \ge 3$ . Let P be a given *h*-short  $(k + 1)$ -gon, where *h* is sufficiently small. We draw a *h*-short path from  $u_1$  to  $u_k$  that splits *P* into a *h*-short *k*-gon  $P_1$ with vertices  $u_1, \ldots, u_k$ , and a *h*-short triangle  $P_2$  with vertices  $u_1, u_k, u_{k+1}$ . Let  $F_i: Q_i \to P_i$ ,  $i = 1, 2$  be the maps<br>querenteed by our inductive by pathecie for n b and the easy sees n 3 where Q is a server k guaranteed by our inductive hypothesis for  $n = k$  and the easy case  $n = 3$ , where  $Q_1$  is a convex  $k$ -gon with vertices  $v_1, v_2, \ldots, v_k \in \mathbb{R}^2$  and  $Q_2$  is a triangle with vertices  $v_1, v_k, v_{k+1}$ . By use of isometries of  $\mathbb{R}^2$ sides from *v*<sub>1</sub> to *v*<sub>*k*</sub> in *Q*<sub>1</sub> and in *Q*<sub>2</sub> are the same, and that  $Q_1$  and  $Q_2$  are on opposite sides of this line segment (so the interiors of *Q*<sub>1</sub> and *Q*<sub>2</sub> are the same, and that  $Q_1$  and  $Q_2$  are on interiors of  $Q_1$  and  $Q_2$  are disjoint).

We now let  $(Q', d')$  be the metric space formed by gluing  $Q_1$  and  $Q_2$  together along  $S = [v_1, v_k]$ , so  $Q' = Q_1 \sqcup_S Q_2$ . Let *Q* be the  $(k + 1)$ -gon with vertices  $v_1, v_2, \ldots, v_{k+1}$  and define  $F: Q \rightarrow P$  by

$$
F(x) = \begin{cases} F_1(x), & x \in Q_1 \cap Q, \\ F_2(x), & x \in Q_2 \cap Q. \end{cases}
$$

Note that the fact that each  $F_i$  is a constant speed map ensures that  $F$  is well-defined.<br>We wish to praye  $A = (B, b, F, G, d', G, \ldots)$  in view of the construction, it suffices to you

We wish to prove  $A_{k+1}(P, h; F, Q, d', C_{k+1})$ . In view of the construction, it suffices to verify [\(4.10\)](#page-7-1), and for this we may assume that  $x \in Q_1$  and  $y \in Q_2$ . Let  $\gamma$  be the geodesic in *Q* connecting *x* to *y*. It follows that  $\gamma = [x, v] \cup [v, y]$ , where  $$ 

Using [\(4.10\)](#page-7-1) for  $P_1$  and  $P_2$  and the definition of the gluing metric  $d'$  on  $Q$ , we thus get

$$
d(F(x), F(y)) \le d(F(x), F(v)) + d(F(v), F(y))
$$
  
\n
$$
\le |x - v| + C_k + |v - y| + C_3
$$
  
\n
$$
= d'(x, y) + C_{k+1}.
$$

We can deduce  $A_{k+1}(P, 0; F, Q, d', 0)$  from the CAT(0) version of our inductive hypothesis by essentially the same<br>------------

argument. If *<sup>Q</sup>* happens to be convex, we are done with the proof so assume that *<sup>Q</sup>* is not convex. Then the interior angle at ei[ther](#page-3-4) *v*<sub>1</sub> or *v*<sub>*k*</sub> exceeds *π*. Assume without loss of generality that the interior angle at *v*<sub>1</sub> is larger than *π*. By Corollary 2.6, the union of the two geodesic segments  $[v_{k+1}, v_1]$  and  $[v_1, v_2]$  is also a geodesic segment and so, by eliminating  $v_1$  as a vertex, we may consider Q to be a geod[es](#page-9-2)ic  $k$ -gon with vertices  $v_2, v_3, \ldots, v_{k+1}$ . We also note that Q is CAT(0) since  $Q_1$  and  $Q_2$  are CAT(0) and the gluing set  $[v_1, v_k]$  is convex; see [3, II.11.1]. Applying the CAT(0) version of our induction assumption to  $Q$ , we get a map  $G: R \to Q$ , where  $R$  is a convex  $k$ -gon in  $\mathbb{R}^2$  with vertices  $w_2, w_3, \ldots, w_{k+1}$  satisfying:

$$
v_i = G(w_i), \t 2 \le i \le k+1,
$$
  
\n
$$
|v_{i-1} - v_i| = |w_{i-1} - w_i|, \t 3 \le i \le k+1,
$$
  
\n
$$
|v_2 - v_{k+1}| \le |w_2 - w_{k+1}|,
$$
  
\n
$$
|G(y) - v_i| = |y - w_i|, \t y \in R, w_i \text{ a vertex adjacent to } y,
$$
  
\n
$$
|G(y) - G(z)| \le |y - z|, \t y, z \in Q.
$$

We now view *<sup>R</sup>* as a convex (*<sup>k</sup>* + 1)-gon by identifying *<sup>G</sup><sup>−</sup>*<sup>1</sup> (*v*1) as an extra vertex (with interior angle *<sup>π</sup>*). Then *<sup>F</sup> ◦ <sup>G</sup>* is the inductive hypothesis for  $n = k + 1$  and we are done with the proof.

For completeness we state a CAT(0) variant of Theorem [1.1.](#page-1-1)

## *Theorem 4.12.*

**VERSITA** 

*A complete geodesic space* (*X, d*) *satisfies the n-point condition for fixed <sup>n</sup> <sup>≥</sup>* <sup>4</sup> *if and only if it is CAT(0).*

**Proof.** Since Theorem [A](#page-0-0) already tells us that the 4-point condition is equivalent to CAT(0), it suffices to prove that CAT(0) implies the *n*-point condition for each *n* > 4. But this follows from the CAT(0) version of our inductive hypothesis which was established in the proof for all *n*  $\in \mathbb{N}$ . which was established in the proof for all *<sup>n</sup> <sup>∈</sup>* <sup>N</sup>.

#### *Remark 4.13.*

By examining the above proof, we see that if *X* is *C*-rCAT(0; \*), then *X* is *C'*-rCAT(0; *H'*) with *C'* = 3*C* + 2 $\sqrt{3\epsilon}$ ,  $0 < \varepsilon \leq 1$ , and

<span id="page-8-0"></span>
$$
H'(x, y, z) := \frac{\varepsilon}{1 \vee d(x, y) \vee d(x, z) \vee d(y, z)}.
$$
\n(4.14)

Taking  $\varepsilon = 1$ , this slightly strengthens [\[1,](#page-9-3) Corollary 4.4] which states that *C*-rCAT(0; *\**) implies *C*'-rCAT(0) for *C*'<br>2*C*  $\pm 2 \pm \sqrt{2}$ , Also interacting is the sess  $\varepsilon = 1$  A (*C*<sup>2</sup>/2)), this shows that the Fraking  $\varepsilon = 1$ , this stightly strengthens [1, Corollary 4.4] which states that C-rCAT(0; *A*) implies C-rCAT(0) for C .—<br>3*C* + 2 +  $\sqrt{3}$ . Also interesting is the case  $\varepsilon = 1 \land (C^2/3)$ : this shows that the *C*-rCAT(0 implies the (5*C*)-rCAT(0; *H'*) condition with the explicit *H'* given by [\(4.14\)](#page-8-0).

As mentioned in the I[ntr](#page-9-2)oduction, CAT(0) is preserved by various limit operations, including pointed Gromov-Hausdorff<br>limits and ultralimits [3, 11.3.10]. The trick is to use the 4-point condition and the concept of a 4-po similar argument, with the 4-point condition replaced by our rough 5-point condition, will give us similar results for similar argument, with the 4-point condition replaced by our rough 5-point condition, will give us similar results for rCAT(0) spaces. We begin with a definition of *<sup>n</sup>*-point limits.

### *Definition 4.15.*

A metric space  $(X, d)$  is an *n*-point limit of a sequence of metric spaces  $(X_m, d_m)$ ,  $m \in \mathbb{N}$ , if for every  $\{x_i\}_{i=1}^n \subset X$ , and  $\varepsilon > 0$ , there exist infinitely many integers  $m$  and points  $x_i(m) \in X_m$ ,  $1 \leq i \leq n$ , such that  $|d(x_i,x_j) - d_m(x_i(m),x_j(m))| < \varepsilon$ for  $1 \leq i, j \leq n$ .

We are now ready to state a 5-point limit result. Note that, since any *n*-point limit  $(X, d)$  of  $((X_m, d_m))_{m=1}^{\infty}$  is also an *n*'-point limit of this sequence of spaces for all  $n' \leq n$ , the following result also holds if 5 is replaced by any larger intervals. The result of this sequence of spaces for all  $n' \leq n$ , the following result also hol [int](#page-9-2)eger. The proof of this result, which is very similar to the corresponding result for CAT(0) and 4-point limits given in [3, II.3.9], is included for completeness.

# <span id="page-9-7"></span>*Theorem 4.16.*

Suppose the length space  $(X, d)$  is a 5-point limit of  $(X_m, d_m)$ ,  $m \in \mathbb{N}$ , where  $(X_m, d_m)$  is  $C_m$ -rCAT $(0; *)$  for some constant Suppose the tength space  $(x, y)$  is a 3-point time of  $(x_m, u_m)$ ,  $m \in \mathbb{N}$ , where  $(x_m, u_m)$  is  $c_m$ -refined  $(x, \pi)$  for some constants  $C_m$ . If  $C_m \to 0$ , and  $(X, d)$  is complete, then  $(X, d)$  is a  $\widetilde{C}$ -refined  $\widetilde{C}$ *then*  $(X, d)$  *is a CAT(0) space.* 

*Proof.* Suppose first that  $C_m \leq C$  for all  $m \in \mathbb{N}$ . Let  $(x_i)_{i=1}^5$  be an arbitrary 5-tuple of points in  $(X, d)$ , and suppose that it is the 5 point limit of the 5 tuples  $(x/m)^5$  in  $X \in \mathbb{R}$  is accepted to a sub that it is the 5-point limit of the 5-tuples  $(x_i(m))_{i=1}^\circ$  in  $X_m$ . By passing to a subsequence if necessary, we may assume<br>that d(x(m) x(m)) xd(x,x) for all 1 < i, i < 5 that  $d(x_i(m), x_j(m)) \to d(x_i, x_j)$  for all  $1 \le i, j \le 5$ .<br>By Theorem 4.2, eveny  $(X, d)$  caticfies a  $C'$  r

By Theorem [4.2,](#page-5-4) every  $(X_m, d_m)$  satisfies a *C*'-rough 5-point condition, where *C*' := 3*C*, so there exists a *C*'<br>cubambadding  $(\overline{\kappa}/m) \times (m) \times (m) \times (m) \times (m)$  into  $\mathbb{R}^2$  for all  $m \in \mathbb{N}$ . Since translation subembedding  $(\overline{x}_1(m), \overline{x}_2(m), \ldots, \overline{x}_5(m))$  of  $(x_1(m), x_2(m), \ldots, x_5(m))$  into  $\mathbb{R}^2$ , for all  $m \in \mathbb{N}$ . Since translation is an internet in  $\mathbb{R}^2$  we may assume that the points  $\overline{x}_1(m)$  coincide for all  $m \in \mathbb{N$ isometry in  $\mathbb{R}^2$ , we may assume that the points  $\overline{x}_1(m)$  coincide for all  $m \in \mathbb{N}$ . Thus all 5-tuples are contained in a disk<br>of finite redius and by passing to a subsequence if peasesery we may assume that  $\over$ of finite radius and by passing to a subsequence if necessary we may assume that  $\bar{x}_i(m)$  converges to some point  $\bar{x}_i$ as  $m \to \infty$ , for all  $1 \le i \le m$ . It follows readily that  $(\overline{x}_i)_{i=1}^5$  is a C'-rough subembedding of  $(x_i)_{i=1}^5$  in  $\mathbb{R}^2$ . Thus  $(X, d)$ satisfies the *C'*-rough 5-point condition. By again using Theorem [4.2,](#page-5-4) we deduce that (*X*, *d*) is a *C-rCAT(0) space where*<br> $\widetilde{C} = C' + 2\sqrt{2}$  $\widetilde{C} = C' + 2\sqrt{C}$ 

If in fact  $C_m \to 0$ , then  $(X_m, d_m)$  satisfies a  $(3C_m)$ -rough 5-point condition, and it follows as above that  $(X, d)$  satisfies the<br>O rough 5 point condition, and bance the 4 point condition. This together with completences (as follows from the fact that  $(X, d)$  is a length space) implies that  $(X, d)$  is a CAT(0) space: see [3, II.1.11].

With Theorem [4.16](#page-9-7) in hand, it is now routine to deduce the following corollary.

## <span id="page-9-8"></span>*Corollary 4.17.*

*Suppose* (*X*, *d*) is a length space and suppose ( $X_m$ ,  $d_m$ ),  $m \in \mathbb{N}$ , form a sequence of *C-rCAT*(0) spaces. Writing  $\widetilde{C} = 3C + 2\sqrt{3}$ , the following results hold.

- *(a) If*  $(X, d)$  *is a (pointed or unpointed) Gromov-Hausdorff limit of*  $(X_m, d_m)$  *then*  $(X, d)$  *is a*  $\tilde{C}$ -*rCAT*(0) *space.*
- *(b) If*  $(X, d)$  *is an ultralimit of*  $(X_m, d_m)$ *, then*  $(X, d)$  *is a*  $C$ -*rCAT*(0) *space.*
- *(c) If <sup>X</sup> is rCAT*(0)*, then the asymptotic cone Coneω<sup>X</sup>* := lim*<sup>ω</sup>*(*X, d/m*) *is a CAT(0) space for every non-principal ultrafilter ω.*

Note that in the proo[f o](#page-9-2)f Corollary [4.17\(](#page-9-8)c), we need the fact that Cone*<sup>ω</sup><sup>X</sup>* is complete, but this is true because ultralimits

are always complete [3, I.5.53].<br>In each part of Corollary [4.17,](#page-9-8) the existence of an approximate midpoint for arbitrary *x, y* ∈ *X* (meaning a point *z* such<br>that d(*u* a) *V* d(*u* a) ≤ a l d(*u u*)/2 for fixed but or that  $d(x, z) \vee d(y, z) \leq \varepsilon + d(x, y)/2$  for fixed but arbitrary  $\varepsilon > 0$ ) [follo](#page-9-8)ws easily from the hypotheses[, a](#page-9-2)nd so  $(X, d)$  is easily seen to be a length space if it is complete. Thus Corollary 4.17 generalizes the  $\kappa = 0$  case of [3, II.3.10](1), (2), where the spaces are assumed to be  $CAT(0)$  rather than  $rCAT(0)$  and the limit space  $(X, d)$  is assumed to be complete rather than a length space.
